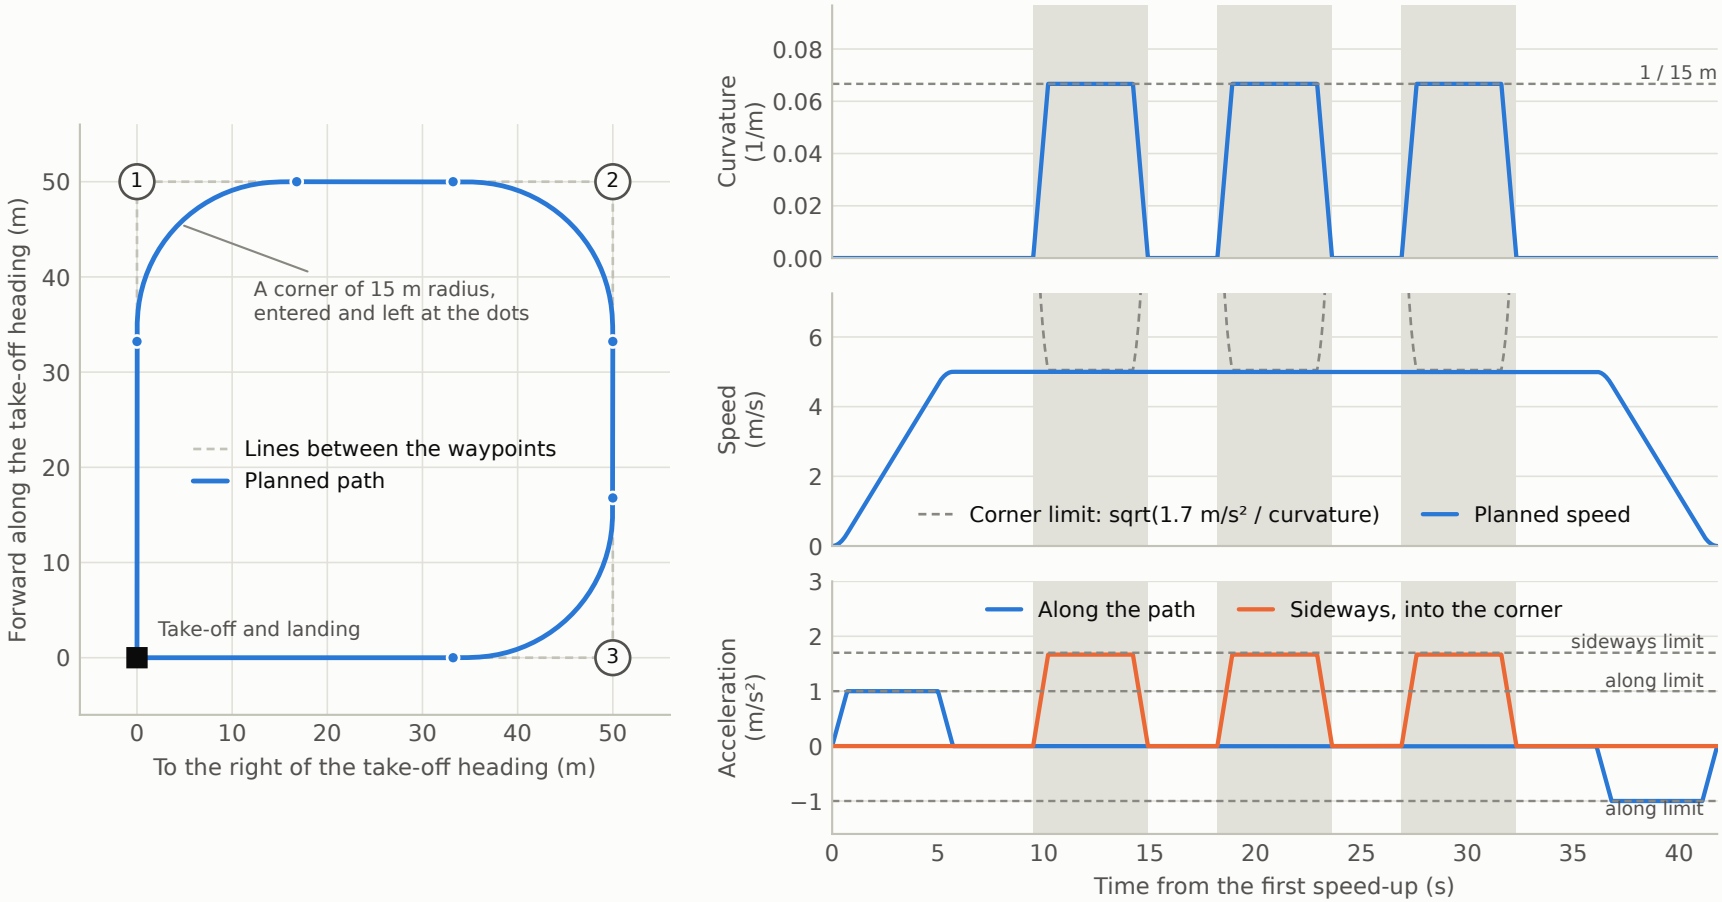
The route is planned before take-off: straight legs, 15 m corners the bank eases into, and no step in speed

The default square at 5 m/s. Each corner's curvature rises and falls over 3.5 m, so the vehicle banks in gradually. Every speed change builds its acceleration up and takes it off over 0.7 s (at most 1 m/s² along, 1.7 m/s² sideways), and the speed reaches zero exactly on the last waypoint.



Computed from missions/2026_year_end/mission.yaml by psi_vtol/trajectory.py; no simulation involved. Darker strips: the corners.
